**Abstract**— In this presents a develop of a 4-parallel pipelined feedforward architecture VLSI implementation for the complex fast Fourier transform (CFFT) with decimation in frequency (DIF) based on the radix-2<sup>3</sup> algorithm with 128 points using folding transformation and register minimization techniques. First the folding architecture for 16-points will be obtained analyzing the lifetime and register allocation for each variable. After that, generalizing this methods, is possible to obtain the 128-points architecture. Furthermore, the final architecture will be optimized using Canonical Sign Digit (CSD) multipliers for stages in which the twiddle factor remains constant for the different instances.

To validate the architecture, a float-point simulator will process a summation of two cosine signals with different frequencies. After that, the input and output of each stage of DFT are carefully quantized with the propose of getting the highest Signal to Quantization Noise Ratio (SQNR) possible.

In addition, different synthesis levels of optimizations will be generated with the purpose of obtaining a architecture implementable at 500 MHz clock frequency using an open-source FreePDK45 of 45 nm CMOS technology. Finally a comparison of speed, power and area for each level of optimization is done in order to obtain the best performance possible.

## I. INTRODUCTION

THE Fast Fourier Transform (FFT) is widely used in different applications fields, particularly in algorithms that involves applying digital signal processing, e.g., calculate the Discrete Fourier Transform (DFT) efficiently. Nowadays is common the use of FFT algorithm for real time applications and parallel-pipelined hardware architecture, this allows to achieve good performance with high throughput rates.

There are two main types of pipelined FFT architectures [1]. On one hand, feedback architectures (FB) which can be divided into Single-path Delay Feedback (SDF) and Multi-path

Figure 1: Types of pipelined FFT architectures for 16 points [?].

Delay Feedback (MDF), both methods transfer data samples between stages serially and use feedback loops. On the other hand, feedforward architectures such as Multi-Path Delay Commutator (MDC) transfers more than one sample per clock cycle and do not use feedback loops.

This work focuses on the design of 4-parallel pipelined architecture radix-2<sup>3</sup> 128-points for Complex FFT-DIF (Decimation In Frequency). Section II, describes the equations that correspond to Butterfly structure of radix-2<sup>3</sup> FFT-DIF. In Section III, the design of a 2-parallel pipelined architecture, radix-2<sup>3</sup> 16-points FFT via folding transformation is presented. In Section IV, the previous design is translate to a 4-parallel, 128-points radix-2<sup>3</sup> DIF complex FFT, and a float-point simulator in *Matlab* is elaborated, to later be compared with a fixed-point model in order to obtain the best Signal to Quantization Noise Ratio (SQNR). In Section VI, different power, area and timing reports with different optimizations such as varying pipelining levels, and the application of canonical signed digit (CSD) are compared to obtain the best performance with a clock frequency of 500MHz. Finally in Section VII some conclusions and discussions are presented.

The first step is obtain the equations that correspond to Butterfly structure of *radix-2*<sup>3</sup> FFT-DIF for 8 points. After that, a 2-parallel pipelined architecture *radix-2*<sup>3</sup> 16-points FFT via folding transformation is deduced with the appropriate *twiddle factors* for each stage and clock cycle over the chain of butterflies on a feedforward architecture MDC. Finally this architecture is translated to a 128-points model.

## II. RADIX-2<sup>3</sup> FFT ALGORITHM

The  $N$ -point DFT of an input sequence  $x[n]$  is defined as:

$$X[k] = \sum_{n=0}^{N-1} x[n] W_N^{nk}, \quad k = 0, 1, \dots, N-1 \quad (1)$$

where  $W_N^{nk} = e^{-j\frac{2\pi}{N}nk}$ .

The FFT based on Cooley-Tukey algorithm is most commonly used in order to compute the DFT efficiently, this allows us reduce the number of operations from  $O(N^2)$  for the DFT to  $O(N \log_2 N)$  for the FFT. Direct computation of the DFT is basically inefficient primarily because it does not exploit the symmetry and periodicity properties of the phase factor  $W_N$ , these two properties are:

$$\text{Symmetry property: } W_N^{k+N/2} = -W_N^k \quad (2)$$

$$\text{Periodicity property: } W_N^{k+N} = W_N^k \quad (3)$$

The development of computationally efficient algorithms for DFT is possible if a *Divide and Conquer* approach is adopted. This approach is based on the decomposition of an  $N$  point DFT into successively smaller DFTs. In accordance with this, the DFT is calculated in series of  $s = \log_\rho N$  stages, where  $\rho$  is the base of the *radix*. In this work this factor is two, so the number of stages for 128 points is 7.

There are two methods to design FFT algorithms [2], [3]:

First, applying decimation in time (DIT), this results in a split of the  $N$ -point data sequence  $x[n]$  into two  $N/2$ -point data sequences. Thus, is possible to obtain two different functions by decimating  $x[n]$  by a factor of 2. The decimation of the data sequence can be repeated again and again until the resulting sequences are reduced to one-point sequence. In each decomposition, the basic computing unit that processes the samples is called *butterfly*.

Second, the decimation in frequency algorithm, is obtained by using the divide-and-conquer approach. Is possible to derive the algorithm by splitting the DFT formula into two summations, one of which involves the sum over the first  $N/2$  data points and the second sum involves the last  $N/2$  data points.

In each decomposition, the basic computing unit that processes the samples is called *butterfly*. In general, each butterfly involves one complex multiplication and two complex additions. The main difference between DIT and DIF is the instant in which the multiplication by  $W_N^\phi$  is accomplished, the input samples can be multiplied before or after the split and the samples are later added inside the butterfly structure, as is depicted in Fig.2.

In addition, the input samples in FFT algorithms DIF are organized in natural order but its output has not in order, in

Figure 2: Basic butterflies computation in the decimation in time and frequency.

this case is necessary a circuit for reordering the output data. On the other hand, FFT algorithms DIT is all the opposite, It has not its input in order and its output has a natural order.

Following the methodology presented in [2], is possible to understand and apply the mathematical expressions of *radix-2*<sup>3</sup> DIF explained in [4].

These fundamental equations are in :

$$\begin{aligned} C_{8k+0} &= \sum_{n=0}^{N/8-1} \left\{ [(x_n + x_{n+\frac{N}{2}}) + (x_{n+\frac{N}{4}} + x_{n+\frac{3N}{4}})] + \right. \\ &\quad \left. [(x_{n+\frac{N}{8}} + x_{n+\frac{5N}{8}}) + (x_{n+\frac{3N}{8}} + x_{n+\frac{7N}{8}})] \right\} W_N^{0n} W_N^{nk} \\ C_{8k+4} &= \sum_{n=0}^{N/8-1} \left\{ [(x_n + x_{n+\frac{N}{2}}) + (x_{n+\frac{N}{4}} + x_{n+\frac{3N}{4}})] - \right. \\ &\quad \left. [(x_{n+\frac{N}{8}} + x_{n+\frac{5N}{8}}) + (x_{n+\frac{3N}{8}} + x_{n+\frac{7N}{8}})] \right\} W_N^{4n} W_N^{nk} \\ C_{8k+2} &= \sum_{n=0}^{N/8-1} \left\{ [(x_n + x_{n+\frac{N}{2}}) - (x_{n+\frac{N}{4}} + x_{n+\frac{3N}{4}})] - j \right. \\ &\quad \left. [(x_{n+\frac{N}{8}} + x_{n+\frac{5N}{8}}) - (x_{n+\frac{3N}{8}} + x_{n+\frac{7N}{8}})] \right\} W_N^{2n} W_N^{nk} \\ C_{8k+6} &= \sum_{n=0}^{N/8-1} \left\{ [(x_n + x_{n+\frac{N}{2}}) - (x_{n+\frac{N}{4}} + x_{n+\frac{3N}{4}})] + j \right. \\ &\quad \left. [(x_{n+\frac{N}{8}} + x_{n+\frac{5N}{8}}) - (x_{n+\frac{3N}{8}} + x_{n+\frac{7N}{8}})] \right\} W_N^{6n} W_N^{nk} \\ C_{8k+1} &= \sum_{n=0}^{N/8-1} \left\{ [(x_n - x_{n+\frac{N}{2}}) - j(x_{n+\frac{N}{4}} - x_{n+\frac{3N}{4}})] + W_N^{N/8} \right. \\ &\quad \left. [(x_{n+\frac{N}{8}} - x_{n+\frac{5N}{8}}) - j(x_{n+\frac{3N}{8}} - x_{n+\frac{7N}{8}})] \right\} W_N^n W_N^{nk} \\ C_{8k+5} &= \sum_{n=0}^{N/8-1} \left\{ [(x_n - x_{n+\frac{N}{2}}) - j(x_{n+\frac{N}{4}} - x_{n+\frac{3N}{4}})] - W_N^{N/8} \right. \\ &\quad \left. [(x_{n+\frac{N}{8}} - x_{n+\frac{5N}{8}}) - j(x_{n+\frac{3N}{8}} - x_{n+\frac{7N}{8}})] \right\} W_N^{5n} W_N^{nk} \\ C_{8k+3} &= \sum_{n=0}^{N/8-1} \left\{ [(x_n - x_{n+\frac{N}{2}}) + j(x_{n+\frac{N}{4}} - x_{n+\frac{3N}{4}})] + W_N^{3N/8} \right. \\ &\quad \left. [(x_{n+\frac{N}{8}} - x_{n+\frac{5N}{8}}) + j(x_{n+\frac{3N}{8}} - x_{n+\frac{7N}{8}})] \right\} W_N^{3n} W_N^{nk} \\ C_{8k+7} &= \sum_{n=0}^{N/8-1} \left\{ [(x_n - x_{n+\frac{N}{2}}) + j(x_{n+\frac{N}{4}} + x_{n+\frac{3N}{4}})] - W_N^{3N/8} \right. \end{aligned} \quad (4)$$

Figure 3: Structure of interconnection for  $\text{radix-}2^3$  DIF DFT.

$$\left[ (x_{n+\frac{N}{8}} - x_{n+\frac{5N}{8}}) + j(x_{n+\frac{3N}{8}} - x_{n+\frac{7N}{8}}) \right] \left\{ W_N^{7n} W_N^{nk} \right\}$$

In Fig. 6 and Fig. 7 is shown the equivalent diagram of interconnections and data flows from the equations presented in (4).

The use of higher value radices lead to different amount of rotators. If we compare the quantity of rotators of an architecture  $\text{radix-}2$  FFT with an architecture  $\text{radix-}2^k$  FFT, this last has less number of phase factors.

Figure 4: Data flow graph (DFG) based in equations (4).

The next step is find the suitable rotator factors for the 16 point DFT, the use of the above equations (4) are essential for this design and them are evaluated to get  $C_{8k+i} = \sum_{n=0}^{16/8-1} \{ \cdot \}$ , for  $k = 0, 1$ . The structure for the 16-point DFT is described in Fig. 6 and Fig. 7.

With these first approaches, is possible to applying the divide and conquer strategy by decomposition of a 128-point DFT and calculating each coefficient  $C_{8k+i} = \sum_{n=0}^{128/8-1} \{ \cdot \}$ , for  $k = 0, 1, \dots, (128/8) - 1$ . In this way a sequence in chain of butterflies is obtained with its corresponding rotation factor and the correct index of the samples in witch they must be added or multiplied. With this technique is possible to do a subdivision of butterflies stages, in Fig. 8 can be seen that the 128 point DFT goes through a processes that involve three stages of butterflies to arrive finally to a set of eight DFT where each of one is a 16 point DFT.

#### A. 128 points DFT

With these first approaches is possible the application of the divide and conquer strategy by decomposing the 128-point DFT and calculating each coefficient  $C_{8k+i} = \sum_{n=0}^{128/8-1} \{ \cdot \}$ , for

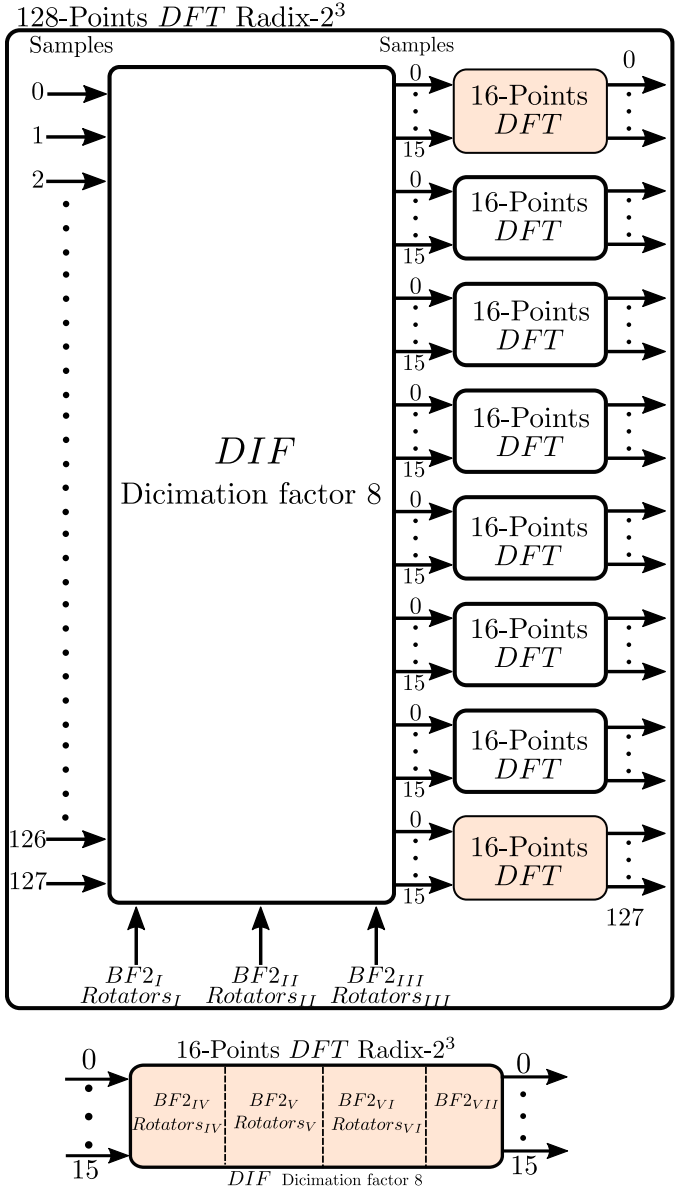

Figure 5: Decomposing a  $\text{radix-}2^3$  128-point DFT.

$k = 0, 1, \dots, (128/8) - 1$ , this way a chain sequence of butterflies obtain together with its corresponding rotation factor and the correct index of the samples in which they must be added or multiplied. With this technique is possible to do a subdivision of butterflies stages, as is shown in Fig. 8, the decomposition of the 128 point DFT involve three stages of butterflies to finally arrive to a set of eight 16 point DFTs. In Fig. 9 the

### III. DESIGN OF A FFT ARCHITECTURE VIA FOLDING TRANSFORMATION

In this section, we illustrate the folding transformation method to derive a 16-point DIF FFT 4-parallel architecture as an example and then, using the same method, we extend it to 128-point architecture. To do this, we will use the architecture proposed in [5], to do the folding transformation and register minimization techniques we will use [6].

Figure 6: Flow graph of a  $\text{radix-}2^3$  16-point DIF DFT

Figure 7: Data flow graph (DFG) for a  $\text{radix-}2^3$  16-point DIF DFT

#### A. 4-Parallel $\text{radix-}2^3$ 16-Points

In Fig. 6 we can see the flow graph of a 16-point DIF FFT  $\text{radix-}2^3$  with main base  $\text{radix-}2$ . The graph is divided into four stages and each of them consist of a set of butterflies and multipliers. The twiddle factor in between the stages indicates a multiplication by  $W_N^k$ , where  $W_N$  denotes the  $N$ th root of unity, with its exponent evaluated modulo  $N$ . This can be represented as a DFG as shown in Fig. 7 where the nodes represents the butterfly computations of the  $\text{radix-}2$  FFT algorithm.

The folding transformation is used on the DFG to derive a pipelined architecture. To do this we need a folding set, which is an ordered set of operations executed by the same functional unit. Each folding set contains  $K$  entries, where  $K$  is called the folding factor. The operation in the  $j$ th position within the folding set (where goes from 0 to  $K - 1$ ) is executed by the functional unit during the time partition, this term is called the folding order.

First we need to derive the folding equations, to do this consider an edge  $e$  connecting the nodes  $U$  and  $V$  with  $w(e)$  delays. Let the executions of the  $l$ th iteration of the nodes  $U$  and  $V$  be scheduled at the time units  $Kl + u$  and  $Kl + v$  respectively, where  $u$  and  $v$  are the folding orders of the nodes  $U$  and  $V$ , respectively. The folding equation for the edge  $e$  is:

$$D_F(U \rightarrow V) = Kw(e) - P_U + v - u \quad (5)$$

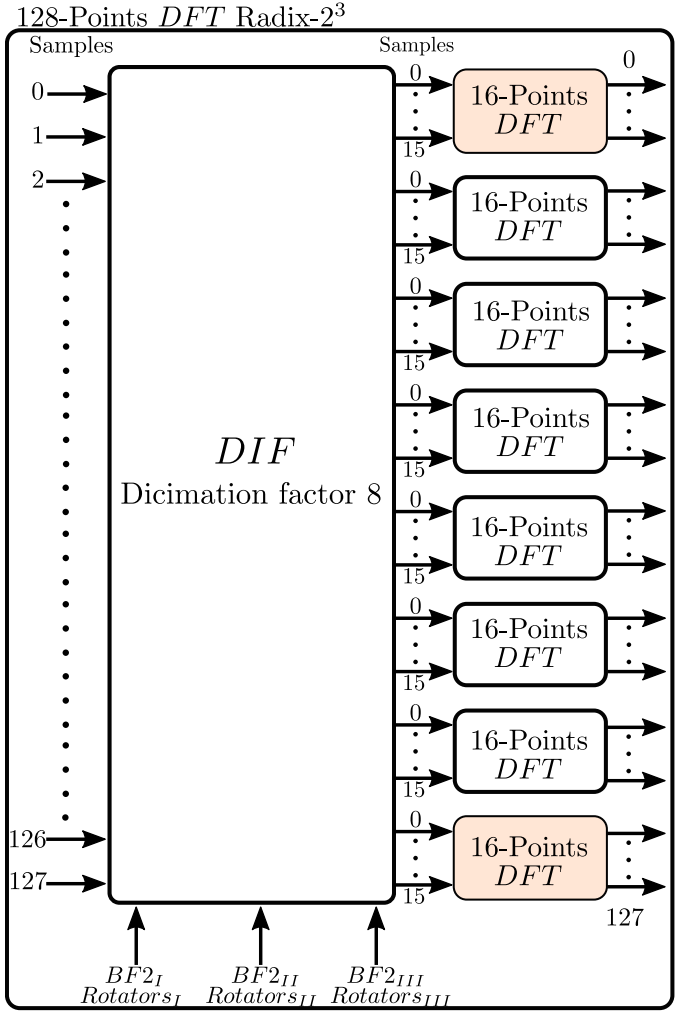

Figure 8: Decomposing a  $\text{radix-}2^3$  128-point DFT.

where  $P_U$  is the number of pipeline stages in the hardware unit which executes the node  $U$ .

Consider folding of the the DFG in Fig. 7 with the folding sets:

$$\begin{aligned} A &= \{A0, A2, A4, A6\} & A' &= \{A1, A3, A5, A7\} \\ B &= \{B1, B3, B5, B7\} & B' &= \{B2, B4, B6, B7\} \\ C &= \{C2, C1, C3, C0\} & C' &= \{C6, C5, C7, C4\} \\ D &= \{D3, D0, D2, D1\} & D' &= \{D7, D4, D6, D5\} \end{aligned} \quad (6)$$

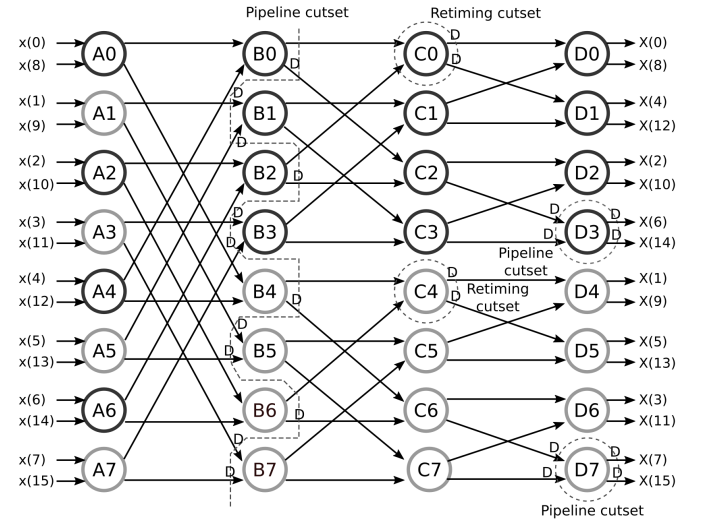

Assuming that the butterfly operations do not have any pipeline stages ( $P_A = P_B = P_C = P_D = 0$ ), the folding equations can be derived for all edges. Thus, we can obtained

Figure 9: Flow graph of a  $\text{radix-}2^3$  128-point DIF DFT

from (5) the expressions *without apply retiming*.

$$\begin{aligned}
 D_F(D0 \rightarrow B0) &= 2 & D_F(D0 \rightarrow B4) &= 2 \\
 D_F(D1 \rightarrow B1) &= 0 & D_F(D1 \rightarrow B5) &= 0 \\
 D_F(D2 \rightarrow B2) &= 2 & D_F(D2 \rightarrow B6) &= 2 \\
 D_F(D3 \rightarrow B3) &= -1 & D_F(D3 \rightarrow B7) &= -1 \\
 D_F(D4 \rightarrow B0) &= 0 & D_F(D4 \rightarrow B4) &= 0 \\
 D_F(D5 \rightarrow B1) &= -1 & D_F(D5 \rightarrow B5) &= -1 \\

 D_F(E7 \rightarrow C5) &= 0 & D_F(E7 \rightarrow C7) &= 1 \\
 D_F(F0 \rightarrow D0) &= -2 & D_F(F0 \rightarrow D1) &= 0 \\
 D_F(F1 \rightarrow D0) &= 0 & D_F(F1 \rightarrow D1) &= 2
 \end{aligned}$$

Figure 10: Data Flow graph (DFG) of a  $\text{radix-}2$  16-point DIF FFT with retiming and pipeline.

For the folded system to be realizable,  $D_F(U \rightarrow V) \geq 0$  must hold for all the edges in the DFG. Retiming and/or pipeline can be applied to satisfy this property, if the DFG in Fig. 7 is pipelined/retimed as shown in Fig. 10 the system is realizable and the folded delays for the edges are given by the equations that represent a folding set *with retiming*.

$$\begin{aligned}
 D_F(D0 \rightarrow B0) &= 2 & D_F(D0 \rightarrow B4) &= 2 \\

 D_F(D4 \rightarrow B0) &= 0 & D_F(D4 \rightarrow B4) &= 0 \\
 D_F(D5 \rightarrow B1) &= 3 & D_F(D5 \rightarrow B5) &= 3 \\
 D_F(D6 \rightarrow B2) &= 0 & D_F(D6 \rightarrow B6) &= 0 \\
 D_F(D7 \rightarrow B3) &= 2 & D_F(D7 \rightarrow B7) &= 2 \\
 D_F(E0 \rightarrow C0) &= 1 & D_F(E0 \rightarrow C2) &= 2 \\
 D_F(E1 \rightarrow C1) &= 1 & D_F(E1 \rightarrow C3) &= 2 \\
 D_F(E2 \rightarrow C0) &= 0 & D_F(E2 \rightarrow C2) &= 1 \\
 D_F(E3 \rightarrow C1) &= 0 & D_F(E3 \rightarrow C3) &= 1 \\
 D_F(E4 \rightarrow C4) &= 1 & D_F(E4 \rightarrow C6) &= 2 \\
 D_F(E5 \rightarrow C5) &= 1 & D_F(E5 \rightarrow C7) &= 2 \\
 D_F(E6 \rightarrow C4) &= 0 & D_F(E6 \rightarrow C6) &= 1 \\
 D_F(E7 \rightarrow C5) &= 0 & D_F(E7 \rightarrow C7) &= 1 \\
 D_F(F0 \rightarrow D0) &= 2 & D_F(F0 \rightarrow D1) &= 4 \\
 D_F(F1 \rightarrow D0) &= 0 & D_F(F1 \rightarrow D1) &= 2 \\
 D_F(F2 \rightarrow D2) &= 2 & D_F(F2 \rightarrow D3) &= 4 \\
 D_F(F3 \rightarrow D2) &= 0 & D_F(F3 \rightarrow D3) &= 2 \\
 D_F(F4 \rightarrow D4) &= 2 & D_F(F4 \rightarrow D5) &= 4 \\
 D_F(F5 \rightarrow D4) &= 0 & D_F(F5 \rightarrow D5) &= 2 \\
 D_F(F6 \rightarrow D6) &= 2 & D_F(F6 \rightarrow D7) &= 4 \\
 D_F(F7 \rightarrow D6) &= 0 & D_F(F7 \rightarrow D7) &= 2
 \end{aligned} \tag{7}$$

We can see that the number of registers required to implement the folding equations in (7) is 80. For minimize the number of registers we use the register minimization technique. If we let the output of node A0 be  $y_{(0)}$  and  $y_{(8)}$  and the output of

Figure 11: Linear lifetime chart for the variables  $y(0), y(1), \dots, y(15)$  for a 16-point FFT architecture.

Figure 12: Linear lifetime chart for the variables  $z(0), z(1), \dots, z(15)$  for a 16-point FFT architecture.

Figure 13: Linear lifetime chart for the variables  $w(0), w(1), \dots, w(15)$  for a 16-point FFT architecture.

the node A1 be  $y(1)$  and  $y(9)$ , applying this successively with the rest of the nodes A we can obtain the linear life time chart for this stage in Fig. 11. Applying this criteria to the rest of the stages we can obtain the life time chart 12 and 13 for the outputs of the nodes B and C respectively, we can see that the numbers of maximum registers in each stage are 8, 4 and 8 respectively, therefore the number of registers is reduced from 80 to 20. More information about this method can be found on [6].

The register allocation tables for the lifetime charts are shown in Fig. 14, 15 and 16 for stage 1, 2 and 3 respectively. In the Fig. 17 and 18 is shown the designations of registers for the stage 1 and 2 respectively used in the allocation tables, the designation for stage 3 are similar for stage 1. The folded architecture in Fig. 20 is synthesized using the folding equations and the register allocation tables. The dataflow for each stage can be see in Tab. I, the control signal for stage 1 and 2 can be implemented by dividing the clock signal to 4 and 2 respectively, for stage 3 the control signal is the same that the stage 1.

The inputs of each folding node are represented with a matrix where the values in the same column are data that flow in parallel and values in the same row flow through the same path in consecutive clock cycles. The first two rows represents the inputs of the superior BF and the others two represents the input of the inferior BF. The same criteria is used for represent

the constants of rotators, where each number  $k$  of the matrix represent a multiplication by  $W_N^k$ .

As we can see in Fig. 20, we suppose that the inputs and output are not ordered, to order these variables extra logic are needed, using more registers and multiplexers.

The different types of rotators used in Fig. 20 are shown in Fig. 19, the description of each of them can be found below.

- Trivial rotator: They can be carried out by interchanging the real and imaginary components and/or changing the sign of the data.
- Constant CSD rotator: They can be carried out by interchanging the real and imaginary components and a multiplication by a unique constant fractional number, in this case we will use a CSD multiplier to perform the area utilized.
- General rotator: They can be carried out by interchanging

#### IV. 4-PARALLEL RADIX-2<sup>3</sup> 128-POINTS

Based on Figure 4 and assigning the name of nodes similar to Fig. 7, i.e. for the first stage A0, A1, ..., A63, for second stage B0, B1, ..., B63 and so on, is possible to obtain a folding set

Figure 19: Symbols used for the different types of rotators

similar to (6) as shown in Table II. After that, is necessary to obtain the folding equations for 128-ponits and apply the same procedure used with the 4-Parallel radix-2<sup>3</sup> 16-Points. The final architecture can be seen in Fig. 21.

#### V. IMPLEMENTATION

##### A. Implementation of a 128-point FFT

In this section we are going to begin with the process of how accomplish the implementation of our 4-parallel architecture for the computation of 128-point radix-2<sup>3</sup> DIF complex FFT. First, we wrote a *MATLAB* simulator to validate the operation of our design and the design presented in [7], [8]. Therefore, we can have a reference architecture for compare the design that we deduce. After that, we take all these information to generate a Synthesizable *Verilog* code with different levels of optimizations with a powerful tool like *Synopsys* to get a final design integrated of Standard Cells at 45nm [9].

##### B. Floating and Fixed point Simulator

The input signal Fig. 23 to our architecture will be a mixture of sinusoid signals with two frequency values, theses signal will be normalizing to the unity and in this way we can have a test bench design.

$$\begin{aligned} x'[n] &= \cos(2\pi f_1 n T_s) + \cos(2\pi f_2 n T_s) \\ x[n] &= x'[n] / \max\{x'[n]\} \end{aligned} \quad (8)$$

where  $f_1 = 100\text{Hz}$ ,  $f_2 = 1000\text{Hz}$  and  $T_s$  is the sampled period.

In each stage of the Fig. 22, input samples that propagate stage by stage will be carefully quantized with the purpose of getting a high SQNR (Signal to Quantization Noise Ratio).

$$SQNR_{dB} = 10 \log_{10} \left( \frac{\text{Var}\{\text{Signal}_{FloatPoint}\}}{\text{Var}\{\text{Signal}_{FloatPoint} - \text{Signal}_{FixedPoint}\}} \right)$$

SQNR computation represents the logarithmic relationship between float signal variance over error variance from an signal given.

The input signal  $x[n]$  is quantized with a value of  $S(10, 9)$ , that representation means a number signed (S) with 10 total bits and 9 fractional bits. The value calculated of SQNR for the input is  $56.9dB$ . Following the same steps, we can compute the SQNR for the *twiddle* factors and the architecture's output.

Twiddle factors are quantized with a relation of  $S(11, 9)$  and the complex output signal  $X[k]$  with  $S(22, 15)$ . Output quantization for the real part is  $46.8dB$  and for the imaginary part  $47.3dB$ . In general, a value of quantization close to  $50dB$  is a good approximation. Out signal from our *MATLAB* fixed-point model from the architecture in Fig. 22 the output signal is given in Fig. 24, that represents a first approach in our calculation of a DFT without optimization.

The combination between latencies (delays registers) and switches in all stages in Fig. 22 is the equivalent circuit shows

in Fig. 25, that is used to appropriately order samples in each butterfly's input.

Whole elements on the architecture such as multipliers and butterflies are complex as Fig. 26 and 27. On an implementation is essential divide the signal in its real and imaginary part with the purpose of process them independently. A *general rotator* (full complex multiplier) generate a real and imaginary component that is composed by a real multiplication on one addition, but a *trivial rotator* only change the components of a complex signal. These relations are important at the moment of doing the quantization process to ensure an appropriate quantity of bits.

### C. Verilog (HDL) Model

In this subsection we are going to talk about the different design instances to model the DFT in hardware. We made four design implementations with the purpose of have a global view of optimization levels to achieve the requested *Timing* at a working frequency of 500MHz obtained from the synthesis processes.

In the first instance of design was made from the base design showed in Fig. 22, this hardware model has butterflies modules that work in combination with multipliers and each multiplier has associated a memory block that contains twiddle factors. In this first approach all multipliers are *full*, each stage

has a control module that enable and disable the inversion of the switching block, this control signal is also sent to the multipliers to work synchronously with the switching. To avoid the bit growth generated by the addition and multiplication, a quantization block is necessary, the quantizer consisted of saturation and truncate operations.

In the second place with the goal of minimize the *critical path* in our design, we add *pipelined* registers after quantization blocks. In the third case of implementation incorporate *trivial* multipliers, imaginary multiplication by  $-1j$ , with this kind of operation we can reduce the size of the binary word.

In the fourth level of optimization showed in Fig. 22, we place inside each butterfly blocks an internal pipelined

to improve the required timing. Lastly, the full multipliers from stage two and five are modified to efficiently work with constant coefficients, these new multipliers are *CSD* because the twiddle factors in these stages are always  $-je^{-j\frac{\pi}{4}}$  and  $e^{-j\frac{\pi}{4}}$ .

## VI. RESULTS

All designs were implemented with different levels of optimization to accomplish the desired working frequency. The design instances were synthesized by Synopsys tool in order to build an interconnection of Standard Cells to get and generate a complete set of *timing-area-power report* showed in Table ??, IV, V and VI. According to the first results, data arrival time is greater than minimum period established 2ns and we can detected that there is a time Violated, with this first approach we decide make a set of optimizations to folding architecture as a pipelined cutset between stages of DFT. In this way as we can see in Table VI, we reduced power, area and timing.

In contrast with the first instance of design, we found in the last case of implementation a slack of time equal to zero, that means the clock period satisfy the time constraint at 500MHz.

## VII. CONCLUSIONS

This work has presented a VLSI Implementation of a Pipelined 128 points 4-Parallel radix- $2^3$  FFT Architecture via Folding Transformation. The Fourier Transform without folding technique processes 128 entry points of samples which are ordered but its output are disordered and it is necessary a reordering circuit. In the other hand a Fourier Transform with folding technique also needs a reordering circuit in the input. This circuit present an additional area and power consumption

to be considered in the final design.

The folding transformation applied reduce significantly (equal to the folded factor, i.e. 64 times) the number of functional units, and therefore the silicon area, and power consumption at the expense of increasing the computation time by the same factor. Therefore is necessary to add pipeline cutsets and a careful quantization on each stage of the design in order to achieve the required sample period with an acceptable SNR.

Folding technique, in this case, results in an architecture that uses a large number of register, to avoid this is necessary to apply a register minimization technique and allocate data to these registers. The number of registers applying this method is reduced significantly. This results in a final design with less area and power consumption.

The number of DFT points is related with the radix-base, we can write as  $radix-8$ , this representation can be expressed as  $radix-2^3$  that means we can decompose in smaller radices with main base-2, an advantage of using a high radix is reduced the number of multipliers at expense of increase the routing.

Our design has implemented a quantizer block which works with saturation and truncated, the round method was not used because we reached a high SQNR. Lastly a series of optimization were necessary to accomplish the required frequency. The DFT implementation without any optimization level got to work at 166MHz, applying pipelines cutsets and quantization blocks, the final architecture is implementable at the required clock frequency (500 MHz) at the cost of incrementing the numbers of sequential cells. Finally, with the CSD multipliers, is possible to reduce the combinational cells significantly, resulting in a more efficient design.
